Julia Warnings:

1. For a function `foo(x::Vector)` with 1 input argument, it is not neccessary to do `df_dx = FD.jacobian(_x -> foo(_x), x)`. Instead you can just do `df_dx = FD.jacobian(foo, x)`. If you do the first one, it can dramatically slow down your compliation time.

2. Do not define functions inside of other functions like this:

```julia
function foo(x)
    # main function foo

    function body(x)
        # function inside function (DON'T DO THIS)
        return 2*x
    end

    return body(x)
end
```
This will also slow down your compilation time dramatically.

Q1: Finite-Horizon LQR (50 pts)

For this problem we are going to consider a "double integrator" for our dynamics model. This system has a state $x \in \mathbb{R}^4$, and control $u \in \mathbb{R}^2$, where the state describes the 2D position p and velocity v of an object, and the control is the acceleration a of this object. The state and control are the following:

$$x = [p_1, p_2, v_1, v_2] \quad (1)$$
$$u = [a_1, a_2] \quad (2)$$

And the continuous time dynamics for this system are the following:

$$\dot{x} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} x + \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{bmatrix} \qquad (3)u$$

Part A: Discretize the model (5 pts)

Use the matrix exponential (`exp` in Julia) to discretize the continuous time model. See the first recitation if you're unsure of what to do.

In [2]:
```
# double integrator dynamics
function double_integrator_AB(dt)::Tuple{Matrix,Matrix}
    Ac = [0 0 1 0;
          0 0 0 1;
          0 0 0 0;
          0 0 0 0.]
    Bc = [0 0;
          0 0;
          1 0;
          0 1]
    nx, nu = size(Bc)

    # TODO: discretize this linear system using the Matrix Exponential
    matrixExp = exp([Ac*dt Bc*dt; zeros(nu, nx+nu)])
    A = matrixExp[1:nx, 1:nx]
    B = matrixExp[1:nx, (nx+1):end]

    @assert size(A) == (nx,nx)
    @assert size(B) == (nx,nu)

    return A, B
end
```

Part B: Finite Horizon LQR via Convex Optimization (15 pts)

We are now going to solve the finite horizon LQR problem with convex optimization. As we went over in class, this problem requires $Q \in S_+$ (Q is symmetric positive semi-definite) and $R \in S_{++}$ (R is symmetric positive definite). With this, the optimization problem can be stated as the following:

$$\min_{x_{1:N},u_{1:N-1}} \quad \sum_{i=1}^{N-1} \left[\frac{1}{2}x_i^T Q x_i + \frac{1}{2}u_i^T R u_i\right] + \frac{1}{2}x_N^T Q_f x_N \tag{4}$$

$$\text{st} \quad x_1 = x_{\text{IC}} \tag{5}$$

$$x_{i+1} = Ax_i + Bu_i \quad \text{for } i = 1,2,\ldots,N-1 \tag{6}$$

This problem is a convex optimization problem since the cost function is a convex quadratic and the constraints are all linear equality constraints. We will setup and solve this exact problem using the `Convex.jl` modeling package. (See 2/16 Recitation video for help with this package. Notebook is here.) Your job in the block below is to fill out a function `Xcvx,Ucvx = convex_trajopt(A,B,Q,R,Qf,N,x_ic)`, where you will form and solve the above optimization problem.

In [4]:
```
# utilities for converting to and from vector of vectors <-> matrix
function mat_from_vec(X::Vector{Vector{Float64}})::Matrix
    # convert a vector of vectors to a matrix
    Xm = hcat(X...)
    return Xm
end
function vec_from_mat(Xm::Matrix)::Vector{Vector{Float64}}
    # convert a matrix into a vector of vectors
    X = [Xm[:,i] for i = 1:size(Xm,2)]
    return X
end
"""
X,U = convex_trajopt(A,B,Q,R,Qf,N,x_ic; verbose = false)

This function takes in a dynamics model x_{k+1} = A*x_k + B*u_k
and LQR cost Q,R,Qf, with a horizon size N, and initial condition
x_ic, and returns the optimal X and U's from the above optimization
problem. You should use the `vec_from_mat` function to convert the
solution matrices from cvx into vectors of vectors (vec_from_mat(X.value))
"""
function convex_trajopt(A::Matrix,       # A matrix
                        B::Matrix,       # B matrix
                        Q::Matrix,       # cost weight
                        R::Matrix,       # cost weight
                        Qf::Matrix,      # term cost weight
                        N::Int64,        # horizon size
                        x_ic::Vector;    # initial condition
                        verbose = false
                        )::Tuple{Vector{Vector{Float64}},Vector{Vector{Float64}}}

    # check sizes of everything
    nx,nu = size(B)
    @assert size(A) == (nx, nx)
    @assert size(Q) == (nx, nx)
    @assert size(R) == (nu, nu)
    @assert size(Qf) == (nx, nx)
    @assert length(x_ic) == nx

    # TODO:

    # create cvx variables where each column is a time step
    # hint: x_k = X[:,k], u_k = U[:,k]
    X = cvx.Variable(nx, N)
    U = cvx.Variable(nu, N - 1)

    # create cost
```

```julia
    # hint: you can't do x'*Q*x in Convex.jl, you must do cvx.quadform(x,Q)
    # hint: add all of your cost terms to `cost`
    cost = 0
    for k = 1:(N-1)
        xk = X[:, k]
        uk = U[:, k]
        cost += 0.5*cvx.quadform(xk, Q)
        cost += 0.5*cvx.quadform(uk, R)
    end

    # add terminal cost
    cost += 0.5*cvx.quadform(X[:, N], Qf)

    # initialize cvx problem
    prob = cvx.minimize(cost)

    # TODO: initial condition constraint
    # hint: you can add constraints to our problem like this:
    # prob.constraints += (Gz == h)

    #Add initial condition constraint
    prob.constraints += X[:,1] == x_ic

    #Add dynamics constraints
    for k = 1:(N-1)
        prob.constraints += X[:, k+1] == A*X[:, k] + B*U[:, k]
    end

    # solve problem (silent solver tells us the output)
    cvx.solve!(prob, ECOS.Optimizer; silent_solver = !verbose)

    if prob.status != cvx.MathOptInterface.OPTIMAL
        error("Convex.jl problem failed to solve for some reason")
    end

    # convert the solution matrices into vectors of vectors
    X = vec_from_mat(X.value)
    U = vec_from_mat(U.value)

    return X, U
end
```

Out[4]: convex_trajopt

Now let's solve this problem for a given initial condition, and simulate it to see how it does:

In [5]:

```julia
@testset "LQR via Convex.jl" begin

    # problem setup stuff
    dt = 0.1
    tf = 5.0
    t_vec = 0:dt:tf

```

Bellman's Principle of Optimality

Now we will test Bellman's Principle of optimality. This can be phrased in many different ways, but the main gist is that any section of an optimal trajectory must be optimal. Our original optimization problem was the above problem:

$$
\begin{aligned}
\min_{x_{1:N},u_{1:N-1}} \quad & \sum_{i=1}^{N-1}\left[\frac{1}{2}x_i^TQx_i+\frac{1}{2}u_i^TRu_i\right]+\frac{1}{2}x_N^TQ_fx_N && (7)\\
\text{st} \quad & x_1 = x_{\text{IC}} && (8)\\
& x_{i+1} = Ax_i + Bu_i \quad \text{for } i = 1,2,\ldots,N-1 && (9)
\end{aligned}
$$

which has a solution $x^*_{1:N}, u^*_{1:N-1}$. Now let's look at optimizing over a subsection of this trajectory. That means that instead of solving for $x_{1:N}, u_{1:N-1}$, we are now solving for $x_{L:N}, u_{L:N-1}$ for some new timestep $1 < L < N$. What we are going to do is take the initial condition from x^*_L from our original optimization problem, and setup a new optimization problem that optimizes over $x_{L:N}, u_{L:N-1}$:

$$
\begin{aligned}
\min_{x_{L:N},u_{L:N-1}} \quad & \sum_{i=L}^{N-1}\left[\frac{1}{2}x_i^TQx_i+\frac{1}{2}u_i^TRu_i\right]+\frac{1}{2}x_N^TQ_fx_N && (10)\\
\text{st} \quad & x_L = x^*_L && (11)\\
& x_{i+1} = Ax_i + Bu_i \quad \text{for } i = L,L+1,\ldots,N-1 && (12)
\end{aligned}
$$

In [6]:

```
@testset "Bellman's Principle of Optimality" begin

    # problem setup
    dt = 0.1
    tf = 5.0
    t_vec = 0:dt:tf
    N = length(t_vec)
    A,B = double_integrator_AB(dt)
    nx,nu = size(B)
    x0 = [5,7,2,-1.4] # initial condition
    Q = diagm(ones(nx))
    R = diagm(ones(nu))
    Qf = 5*Q

    # solve for X_{1:N}, U_{1:N-1} with convex optimization
    Xcvx1,Ucvx1 = convex_trajopt(A,B,Q,R,Qf,N,x0; verbose = false)

    # now let's solve a subsection of this trajectory
    L = 18
    N_2 = N - L + 1

    # here is our updated initial condition from the first problem
    x0_2 = Xcvx1[L]
    Xcvx2,Ucvx2 = convex_trajopt(A,B,Q,R,Qf,N_2,x0_2; verbose = false)

    # test if these trajectories match for the times they share
    U_error = Ucvx1[L:end] .- Ucvx2
    X_error = Xcvx1[L:end] .- Xcvx2
    @test 1e-14 < maximum(norm.(U_error)) < 1e-3
    @test 1e-14 < maximum(norm.(X_error)) < 1e-3

    # ---------------------------plotting -----------------------------
    X1m = mat_from_vec(Xcvx1)
    X2m = mat_from_vec(Xcvx2)
    plot(X2m[1,:],X2m[2,:], label = "optimal subtrajectory", lw = 5, ls = :dot)
    display(plot!(X1m[1,:],X1m[2,:],
                  title = "Trajectory in State Space",
                  ylabel = "x₂", xlabel = "x₁", label = "full trajectory"))
    # ---------------------------plotting -----------------------------
```

```julia
    @test isapprox(Xcvx1[end], [-0.02285990, -0.07140241, -0.21259, -0.1540299], rtol =

Part C: Finite-Horizon LQR via Ricatti (10 pts)

Now we are going to solve the original finite-horizon LQR problem:

$$\min_{x_{1:N}, u_{1:N-1}} \quad \sum_{i=1}^{N-1} \left[\frac{1}{2} x_i^T Q x_i + \frac{1}{2} u_i^T R u_i \right] + \frac{1}{2} x_N^T Q_f x_N \tag{13}$$

$$\text{st} \quad x_1 = x_{\text{IC}} \tag{14}$$

$$x_{i+1} = A x_i + B u_i \quad \text{for } i = 1, 2, \ldots, N-1 \tag{15}$$

with a Ricatti recursion instead of convex optimization. We describe our optimal cost-to-go function (aka the Value function) as the following:

$$V_k(x) = \frac{1}{2} x^T P_k x$$

.

In [7]:
```julia
"""
use the Ricatti recursion to calculate the cost to go quadratic matrix P and
optimal control gain K at every time step. Return these as a vector of matrices,
where P_k = P[k], and K_k = K[k]
"""
function fhlqr(A::Matrix, # A matrix
               B::Matrix, # B matrix
               Q::Matrix, # cost weight
               R::Matrix, # cost weight
```

```julia
              Qf::Matrix,# term cost weight
              N::Int64   # horizon size
              )::Tuple{Vector{Matrix{Float64}}, Vector{Matrix{Float64}}} # return two m

    # check sizes of everything
    nx,nu = size(B)
    @assert size(A) == (nx, nx)
    @assert size(Q) == (nx, nx)
    @assert size(R) == (nu, nu)
    @assert size(Qf) == (nx, nx)

    # instantiate S and K
    P = [zeros(nx,nx) for i = 1:N]
    K = [zeros(nu,nx) for i = 1:N-1]

    # initialize S[N] with Qf
    P[N] = deepcopy(Qf)

    # Ricatti
    for i = 1:N-1
        k = N-i
        K[k] = (R+B'*P[k+1]*B)\B'*P[k+1]*A
        P[k] = Q + A'*P[k+1]*(A - B*K[k])
    end

    return P, K
end
```

Out[7]: fhlqr

In [8]:

```julia
@testset "Convex trajopt vs LQR" begin

    # problem stuff
    dt = 0.1
    tf = 5.0
    t_vec = 0:dt:tf
    N = length(t_vec)
    A,B = double_integrator_AB(dt)
    nx,nu = size(B)
    x0 = [5,7,2,-1.4] # initial condition
    Q = diagm(ones(nx))
    R = diagm(ones(nu))
    Qf = 5*Q

    # solve for X_{1:N}, U_{1:N-1} with convex optimization

Part D: Why LQR is so great (10 pts)

Now we are going to emphasize two reasons why the feedback policy from LQR is so useful:

1. It is robust to noise and model uncertainty (the Convex approach would require re-solving of the problem every time the new state differs from the expected state (this is MPC, more on this in Q3)
2. We can drive to any achievable goal state with $u = -K(x - x_{goal})$

First we are going to look at a simulation with the following white noise:

$$x_{k+1} = Ax_k + Bu_k + \text{noise}$$

Where noise $\sim \mathcal{N}(0, \Sigma)$.

In [10]:
```
@testset "Why LQR is great reason 1" begin

    # problem stuff
    dt = 0.1
    tf = 7.0
    t_vec = 0:dt:tf
    N = length(t_vec)
    A,B = double_integrator_AB(dt)
    nx,nu = size(B)
    x0 = [5,7,2,-1.4] # initial condition
    Q = diagm(ones(nx))
    R = diagm(ones(nu))
    Qf = 10*Q

    # solve for X_{1:N}, U_{1:N-1} with convex optimization
    Xcvx,Ucvx = convex_trajopt(A,B,Q,R,Qf,N,x0; verbose = false)
    P, K = fhlqr(A,B,Q,R,Qf,N)
```

```julia
    # now let's simulate using Ucvx
    Xsim_cvx = [zeros(nx) for i = 1:N]
    Xsim_cvx[1] = 1*x0
    Xsim_lqr = [zeros(nx) for i = 1:N]
    Xsim_lqr[1] = 1*x0
    for i = 1:N-1
        # sampled noise to be added after each step
        noise = [.005*randn(2);.1*randn(2)]

        # simulate cvx control
        Xsim_cvx[i+1] = A*Xsim_cvx[i] + B*Ucvx[i] + noise

        # TODO: use your FHLQR control gains K to calculate u_lqr
        # simulate lqr control
        u_lqr = -K[i]*Xsim_lqr[i]
        Xsim_lqr[i+1] = A*Xsim_lqr[i] + B*u_lqr + noise
    end

Part E: Infinite-horizon LQR (10 pts)

Up until this point, we have looked at finite-horizon LQR which only considers a finite number of timesteps in our trajectory. When this problem is solved with a Ricatti recursion, there is a new feedback gain matrix K_k for each timestep. As the length of the trajectory increases, the first feedback gain matrix K_1 will begin to converge on what we call the "infinite-horizon LQR gain". This is the value that K_1 converges to as $N \to \infty$.

Below, we will plot the values of P and K throughout the horizon and observe this convergence.

In [12]:
```
# half vectorization of a matrix
function vech(A)
    return A[tril(trues(size(A)))]
end
@testset "P and K time analysis" begin

    # problem stuff
    dt = 0.1
    tf = 10.0
    t_vec = 0:dt:tf
    N = length(t_vec)
```

```
    A,B = double_integrator_AB(dt)
    nx,nu = size(B)

    # cost terms
    Q = diagm(ones(nx))
    R = .5*diagm(ones(nu))
    Qf = randn(nx,nx); Qf = Qf'*Qf + I;

    P, K = fhlqr(A,B,Q,R,Qf,N)

    Pm = hcat(vech.(P)...)
    Km = hcat(vec.(K)...)

    # make sure these things converged
    @test 1e-13 < norm(P[1] - P[2]) < 1e-3
    @test 1e-13 < norm(K[1] - K[2]) < 1e-3

    display(plot(t_vec, Pm', label = "",title = "Cost-to-go Matrix (P)", xlabel = "time(
    display(plot(t_vec[1:end-1], Km', label = "",title = "Gain Matrix (K)", xlabel = "ti

end
```
